### **Saving angels: Vital information on Angelshark ecology used to inform the conservation of one of Europe's most endangered sharks**

The angel shark family (Squatinae) is the second most threatened group of sharks and rays in the world. The Angelshark (*Squatina squatina*) was once widespread throughout the Atlantic and Mediterranean Sea, however it has now almost disappeared throughout its natural range, mainly due to overfishing. Today, the Canary Islands is the last refuge for the Angelshark, but here too they are under threat. One key factor preventing effective conservation is lack of detailed scientific information about their ecology.

However, there is still hope to save these angels. The Angel Shark Project, a collaboration between the Zoological Research Museum Alexander Koenig (ZFMK), the University of Las Palmas de Gran Canaria (ULPGC) and the Zoological Society of London (ZSL) have [published](#) the first-ever study, using data collected through POSEIDON (a citizen science program to collect marine biodiversity data in the Canary Islands), to identify the distribution patterns, habitat use and population structure of the Critically Endangered Angelshark (*Squatina squatina*) in its last stronghold: the waters around the Canary Islands.

Eva Meyers (ZFMK) who led the study explains why this information is important. "Understanding the timing of key events and the places where these sharks spend most of their time to find food, pup or mate, are critical to ensure that conservation strategies are implemented effectively. Our results highlight key aggregation areas, in particular in shallow coastal areas that should be included in spatial management plans."

Diving with this unique shark is an extremely popular tourist attraction in the Canaries. In 2014, a citizen science programme was initiated by the Angel Shark Project, to collect data from recreational scuba divers with the aim of better understanding Angelshark distribution and ecology – insights which have fed into this study.

"Involving scuba divers has shown to be a very effective tool to obtain large data sets over a wide geographical area in very short time. Diver knowledge and participation has significantly contributed to this study and has also raised awareness of the status of this endangered shark", says Eva Meyers.

Dr. David Jiménez Alvarado, ULPGC, adds: "The wider status of Angelsharks was not known for a long time in the Canary Islands, as this species is still seen here relatively frequently. Through collaborative research and conservation, this is one part of a wider programme of work to understand and care for this emblematic shark."

The information from this study was used to develop an Angelshark Action Plan for the Canary Islands, launched in December 2016.

“Our Vision of the Action Plan is that Angelsharks in the Canary Islands are abundant and protected in their unique stronghold. The data provided by this study will prove invaluable in moving our collaborative project towards this ambition, whilst also informing similar efforts to conserve other remnant Angelshark populations elsewhere in their natural range. It’s a bold ambition given the species’ current Critically Endangered status but, working in partnership and underpinned by scientific research, one we are determined to achieve.” adds Joanna Barker, ZSL.

To report Angelshark sightings, or learn more about the conservation of this species, visit [www.angelsharkproject.com](http://www.angelsharkproject.com).
